Data Mining Cluster Analysis: Advanced Concepts and Algorithms

Lecture Notes for Chapter 8

Introduction to Data Mining, 2nd Edition by Tan, Steinbach, Karpatne, Kumar

Outline

- Prototype-based
 - Fuzzy c-means
 - Mixture Model Clustering
 - Self-Organizing Maps
- Density-based
 - Grid-based clustering
 - Subspace clustering
- Graph-based
 - Chameleon
 - Jarvis-Patrick
 - Shared Nearest Neighbor (SNN)
- Characteristics of Clustering Algorithms

02/14/2018

Introduction to Data Mining, 2nd Edition

Hard (Crisp) vs Soft (Fuzzy) Clustering

- Hard (Crisp) vs. Soft (Fuzzy) clustering
 - For soft clustering allow point to belong to more than one cluster
 - For K-means, generalize objective function

$$SSE = \sum_{j=1}^{K} \sum_{i=1}^{K} w_{ij} \, dist(x_i, c_j)^2 \qquad \sum_{j=1}^{K} w_{ij} = 1$$

 w_{ij} : weight with which object x_i belongs to cluster c_i

- To minimize SSE, repeat the following steps:
 - Fix c_i and determine w_{ii} (cluster assignment)
 - Fix w_{ij} and recompute c_i
- Hard clustering: w_{ii}∈ {0,1}

02/14/2018

Introduction to Data Mining, 2nd Edition

3

Soft (Fuzzy) Clustering: Estimating Weights

$$SSE(x) = w_{x1}(2-1)^{2} + w_{x2}(5-2)^{2}$$

$$= w_{x1} + 9w_{x2}$$

$$= w_{x1} + 9w_{x2}$$

SSE(x) is minimized when $w_{x1} = 1$, $w_{x2} = 0$

02/14/2018 Introduction to Data Mining, 2nd Edition

Fuzzy C-means

Objective function

$$SSE = \sum_{j=1}^{k} \sum_{i=1}^{m} w_{ij}^{p} dist(x_{i}, c_{j})^{2} \qquad \sum_{j=1}^{k} w_{ij} = 0$$

p: fuzzifier (p > 1)

- w_{ij} : weight with which object x_i belongs to cluster c_i
- p: a power for the weight not a superscript and controls how "fuzzy" the clustering is
- To minimize objective function, repeat the following:
 - ◆ Fix c_i and determinew_{ij}
 - ◆ Fix w_{ij} and recompute c
- Fuzzy c-means clustering: $w_{ij} \in [0,1]$

5

6

 c_2

Fuzzy C-means

 c_1

SSE(x) is minimized when $w_{x1} = 0.9$, $w_{x2} = 0.1$

Introduction to Data Mining, 2nd Edition

Fuzzy C-means

Objective function:

$$SSE = \sum_{j=1}^{k} \sum_{i=1}^{m} w_{ij}^{p} dist(x_{i}, c_{j})^{2} \qquad \sum_{j=1}^{k} w_{ij} = 1$$

- Initialization: choose the weights w_{ij} randomly
- Repeat:

Update centroids:

$$c_{j} = \sum_{i=1}^{m} w_{ij} x_{i} / \sum_{i=1}^{m} w_{ij}$$

- Update weights:

$$w_{ij} = (1/dist(\mathbf{x}_i, \mathbf{c}_j)^2)^{\frac{1}{p-1}} / \sum_{j=1}^k (1/dist(\mathbf{x}_i, \mathbf{c}_j)^2)^{\frac{1}{p-1}}$$

02/14/2018

Introduction to Data Mining, 2nd Edition

9

Hard (Crisp) vs Soft (Probabilistic) Clustering

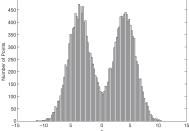

- Idea is to model the set of data points as arising from a mixture of distributions
 - Typically, normal (Gaussian) distribution is used
 - But other distributions have been very profitably used
- Clusters are found by estimating the parameters of the statistical distributions
 - Can use a k-means like algorithm, called the Expectation-Maximization (EM) algorithm, to estimate these parameters
 - Actually, k-means is a special case of this approach
 - Provides a compact representation of clusters
 - The probabilities with which point belongs to each cluster provide a functionality similar to fuzzy clustering.

02/14/2018

Introduction to Data Mining, 2nd Edition

Probabilistic Clustering: Example

 Informal example: consider modeling the points that generate the following histogram.

- Looks like a combination of two normal (Gaussian) distributions
- Suppose we can estimate the mean and standard deviation of each normal distribution.
 - This completely describes the two clusters
 - We can compute the probabilities with which each point belongs to each cluster
 - Can assign each point to the cluster (distribution) for which it $prob(x_i|\Theta) = \frac{1}{\sqrt{2\pi}\sigma} \; e^{-\frac{(x-\mu)^2}{2\sigma^2}}$ is most probable.

02/14/2018

Introduction to Data Mining, 2nd Edition

11

Probabilistic Clustering: EM Algorithm

Initialize the parameters

Repeat

For each point, compute its probability under each distribution Using these probabilities, update the parameters of each distribution Until there is no change

- Very similar to K-means
- Consists of assignment and update steps
- Can use random initialization
 - Problem of local minima
- For normal distributions, typically use K-means to initialize
- If using normal distributions, can find elliptical as well as spherical shapes.

02/14/2018

Introduction to Data Mining, 2nd Edition

Probabilistic Clustering: Updating Centroids

Update formula for weights assuming an estimate for statistical parameters

$$c_j = \sum_{i=1}^m x_i p(C_j \mid x_i) / \sum_{i=1}^m p(C_j \mid x_i) \stackrel{x_i \text{ is a data point}}{c_j \text{ is a cluster}} c_j \text{ is a centroid}$$

- Very similar to the fuzzy k-means formula
 - Weights are probabilities
 - Weights are not raised to a power
 - Probabilities calculated using Bayes rule: $p(C_j|x_i) = \frac{p(x_i|C_j)p(C_j)}{\sum_{l=1}^k p(x_i|C_l)p(C_l)}$
- Need to assign weights to each cluster
 - Weights may not be equal
 - Similar to prior probabilities
 - Can be estimated:

$$p(C_{j}) = \frac{1}{m} \sum_{i=1}^{m} p(C_{j} | \mathbf{x}_{i})$$

02/14/2018

Introduction to Data Mining, 2nd Edition

13

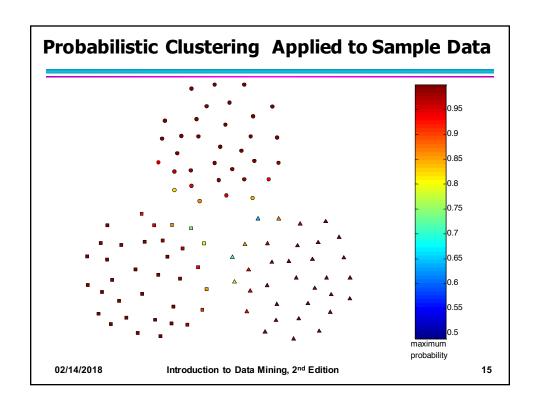

More Detailed EM Algorithm

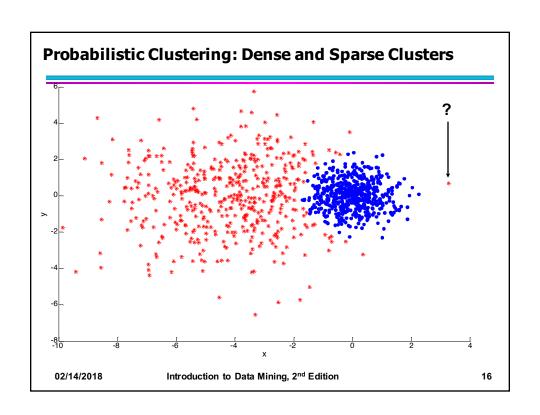

Algorithm 9.2 EM algorithm.

- 1: Select an initial set of model parameters.
 - (As with K-means, this can be done randomly or in a variety of ways.)
- 2: repeat
- 3: **Expectation Step** For each object, calculate the probability that each object belongs to each distribution, i.e., calculate $prob(distribution j | \mathbf{x}_i, \Theta)$.
- 4: **Maximization Step** Given the probabilities from the expectation step, find the new estimates of the parameters that maximize the expected likelihood.
- 5: **until** The parameters do not change.
 (Alternatively, stop if the change in the parameters is below a specified threshold.)

02/14/2018

Introduction to Data Mining, 2nd Edition

Problems with EM

- Convergence can be slow
- Only guarantees finding local maxima
- Makes some significant statistical assumptions
- Number of parameters for Gaussian distribution grows as $O(d^2)$, d the number of dimensions
 - Parameters associated with covariance matrix
 - K-means only estimates cluster means, which grow as O(d)

02/14/2018

SOM: Self-Organizing Maps

- Self-organizing maps (SOM)
 - Centroid based clustering scheme
 - Like K-means, a fixed number of clusters are specified
 - However, the spatial relationship of clusters is also specified, typically as a grid

- Points are considered one by one
- (1,0) (1,1) (1,2)
- Each point is assigned to the closest centroid
- $(2,0) \qquad (2,1) \qquad (2,2)$
- Other centroids are updated based on their nearness to the closest centroid

Kohonen, Teuvo, and Self-Organizing Maps. "Springer series in information sciences." Self-organizing maps 30 (1995).

Introduction to Data Mining, 2nd Edition

19

SOM: Self-Organizing Maps

Algorithm 9.3 Basic SOM Algorithm.

- 1: Initialize the centroids.
- 2: repeat
- 3: Select the next object.
- 4: Determine the closest centroid to the object.
- Update this centroid and the centroids that are close, i.e., in a specified neighborhood.
- 6: until The centroids don't change much or a threshold is exceeded.
- 7: Assign each object to its closest centroid and return the centroids and clusters.
- Updates are weighted by distance
 - Centroids farther away are affected less
- The impact of the updates decreases with each time
 - At some point the centroids will not change much

02/14/2018

Introduction to Data Mining, 2nd Edition

SOM: Self-Organizing Maps

- SOM can be viewed as a type of dimensionality reduction
- If a two-dimensional grid is used, the results can be visualized

23

Issues with SOM

- Computational complexity
- Locally optimal solution
- Grid is somewhat arbitrary

02/14/2018

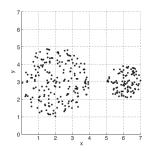

Introduction to Data Mining, 2nd Edition

Grid-based Clustering

A type of density-based clustering

Algorithm 9.4 Basic grid-based clustering algorithm.

- 1: Define a set of grid cells.
- 2: Assign objects to the appropriate cells and compute the density of each cell.
- 3: Eliminate cells having a density below a specified threshold, τ .
- 4: Form clusters from contiguous (adjacent) groups of dense cells.

02/14/2018

Introduction to Data Mining, 2nd Edition

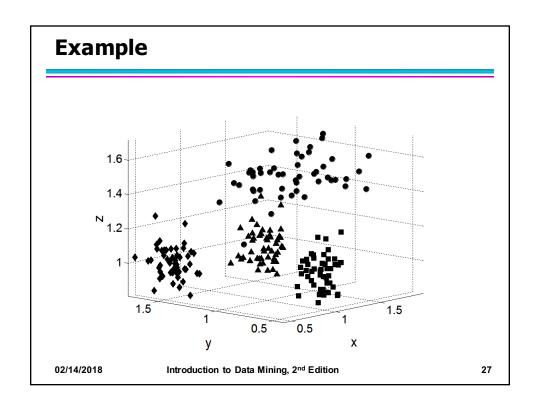

25

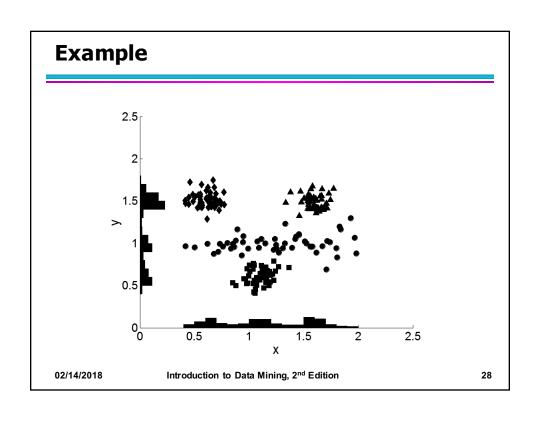

Subspace Clustering

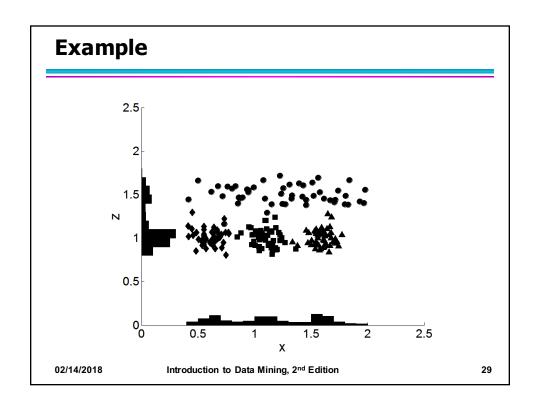

- Until now, we found clusters by considering all of the attributes
- Some clusters may involve only a subset of attributes, i.e., subspaces of the data
 - Example:
 - When k-means is used to find document clusters, the resulting clusters can typically be characterized by 10 or so terms

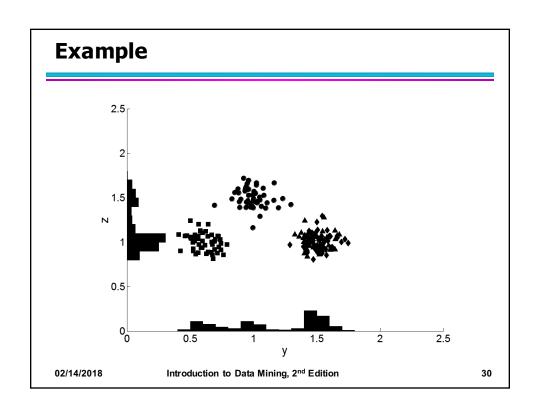

02/14/2018

Introduction to Data Mining, 2nd Edition

Clique Algorithm - Overview

- A grid-based clustering algorithm that methodically finds subspace clusters
 - Partitions the data space into rectangular units of equal volume
 - Measures the density of each unit by the fraction of points it contains
 - A unit is dense if the fraction of overall points it contains is above a user specified threshold, τ
 - A cluster is a group of collections of contiguous (touching) dense units

02/14/2018

Introduction to Data Mining, 2nd Edition

31

Clique Algorithm

- It is impractical to check each volume unit to see if it is dense since there is exponential number of such units
- Monotone property of density-based clusters:
 - If a set of points forms a density based cluster in k dimensions, then the same set of points is also part of a density based cluster in all possible subsets of those dimensions
- Very similar to Apriori algorithm
- Can find overlapping clusters

02/14/2018

Introduction to Data Mining, 2nd Edition

Clique Algorithm

Algorithm 9.5 CLIQUE.

- 1: Find all the dense areas in the one-dimensional spaces corresponding to each attribute. This is the set of dense one-dimensional cells.
- $2: k \leftarrow 2$
- 3: repeat
- 4: Generate all candidate dense k-dimensional cells from dense (k-1)-dimensional cells.
- 5: Eliminate cells that have fewer than ξ points.
- 6: $k \leftarrow k + 1$
- 7: **until** There are no candidate dense k-dimensional cells.
- 8: Find clusters by taking the union of all adjacent, high-density cells.
- 9: Summarize each cluster using a small set of inequalities that describe the attribute ranges of the cells in the cluster.

02/14/2018

Introduction to Data Mining, 2nd Edition

33

Limitations of Clique

- Time complexity is exponential in number of dimensions
 - Especially if "too many" dense units are generated at lower stages
- May fail if clusters are of widely differing densities, since the threshold is fixed
 - Determining appropriate threshold and unit interval length can be challenging

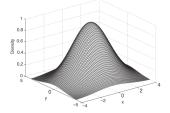

02/14/2018

Introduction to Data Mining, 2nd Edition

Denclue (DENsity CLUstering)

- Based on the notion of kernel-density estimation
 - Contribution of each point to the density is given by an influence or kernel function

$$K(y) = e^{-distance(\mathbf{x}, \mathbf{y})^2/2\sigma^2}$$

Formula and plot of Gaussian Kernel

Overall density is the sum of the contributions of all points

02/14/2018

Introduction to Data Mining, 2nd Edition

35

Introduction to Data Mining, 2nd Edition

37

DENCLUE Algorithm

- Find the density function
- Identify local maxima (density attractors)
- Assign each point to the density attractor
 - Follow direction of maximum increase in density
- Define clusters as groups consisting of points associated with density attractor
- \bullet Discard clusters whose density attractor has a density less than a user specified minimum, ξ
- Combine clusters connected by paths of points that are connected by points with density above ξ

02/14/2018

Introduction to Data Mining, 2nd Edition

Graph-Based Clustering: General Concepts

- Graph-Based clustering uses the proximity graph
 - Start with the proximity matrix
 - Consider each point as a node in a graph
 - Each edge between two nodes has a weight which is the proximity between the two points
 - Initially the proximity graph is fully connected
 - MIN (single-link) and MAX (complete-link) can be viewed in graph terms
- In the simplest case, clusters are connected components in the graph.

02/14/2018

Introduction to Data Mining, 2nd Edition

39

CURE Algorithm: Graph-Based Clustering

- Agglomerative hierarchical clustering algorithms vary in terms of how the proximity of two clusters are computed
 - MIN (single link)
 - susceptible to noise/outliers
 - MAX (complete link)/GROUP AVERAGE/Centroid/Ward's:
 - may not work well with non-globular clusters
- CURE algorithm tries to handle both problems

02/14/2018

Introduction to Data Mining, 2nd Edition

CURE Algorithm

- Represents a cluster using multiple representative points
 - Representative points are found by selecting a constant number of points from a cluster
 - First representative point is chosen to be the point furthest from the center of the cluster
 - Remaining representative points are chosen so that they are farthest from all previously chosen points

02/14/2018

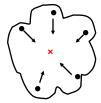

Introduction to Data Mining, 2nd Edition

41

CURE Algorithm

 \bullet "Shrink" representative points toward the center of the cluster by a factor, α

- Shrinking representative points toward the center helps avoid problems with noise and outliers
- Cluster similarity is the similarity of the closest pair of representative points from different clusters

02/14/2018

Introduction to Data Mining, 2nd Edition

CURE Algorithm

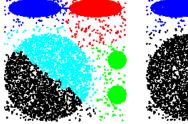

- Uses agglomerative hierarchical scheme to perform clustering;
 - $-\alpha$ = 0: similar to centroid-based
 - $-\alpha$ = 1: somewhat similar to single-link
- CURE is better able to handle clusters of arbitrary shapes and sizes

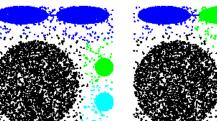

02/14/2018

Introduction to Data Mining, 2nd Edition

Graph-Based Clustering: Chameleon

- Based on several key ideas
 - Sparsification of the proximity graph
 - Partitioning the data into clusters that are relatively pure subclusters of the "true" clusters
 - Merging based on preserving characteristics of clusters

02/14/2018

Introduction to Data Mining, 2nd Edition

47

Graph-Based Clustering: Sparsification

- The amount of data that needs to be processed is drastically reduced
 - Sparsification can eliminate more than 99% of the entries in a proximity matrix
 - The amount of time required to cluster the data is drastically reduced
 - The size of the problems that can be handled is increased

02/14/2018

Introduction to Data Mining, 2nd Edition

Graph-Based Clustering: Sparsification ...

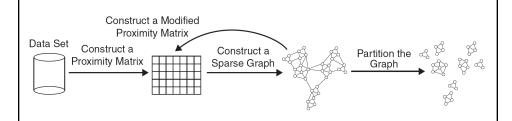

- Clustering may work better
 - Sparsification techniques keep the connections to the most similar (nearest) neighbors of a point while breaking the connections to less similar points.
 - The nearest neighbors of a point tend to belong to the same class as the point itself.
 - This reduces the impact of noise and outliers and sharpens the distinction between clusters.
- Sparsification facilitates the use of graph partitioning algorithms (or algorithms based on graph partitioning algorithms)
 - Chameleon and Hypergraph-based Clustering

02/14/2018

Introduction to Data Mining, 2nd Edition

49

Sparsification in the Clustering Process

02/14/2018

Introduction to Data Mining, 2nd Edition

Limitations of Current Merging Schemes

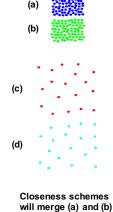

- Existing merging schemes in hierarchical clustering algorithms are static in nature
 - MIN or CURE:
 - Merge two clusters based on their closeness (or minimum distance)
 - GROUP-AVERAGE:
 - Merge two clusters based on their average connectivity

02/14/2018

Introduction to Data Mining, 2nd Edition

51

Limitations of Current Merging Schemes

(a) (b)

Average connectivity schemes will merge (c) and (d)

(d)

02/14/2018

Introduction to Data Mining, 2nd Edition

Chameleon: Clustering Using Dynamic Modeling

- Adapt to the characteristics of the data set to find the natural clusters
- Use a dynamic model to measure the similarity between clusters
 - Main properties are the relative closeness and relative interconnectivity of the cluster
 - Two clusters are combined if the resulting cluster shares certain properties with the constituent clusters
 - The merging scheme preserves self-similarity

02/14/2018

Introduction to Data Mining, 2nd Edition

53

Relative Interconnectivity

• Relative Interconnectivity (RI) is the absolute interconnectivity of two clusters normalized by the internal connectivity of the clusters. Two clusters are combined if the points in the resulting cluster are almost as strongly connected as points in each of the original clusters. Mathematically,

$$RI = \frac{EC(C_i, C_j)}{\frac{1}{2}(EC(C_i) + EC(C_j))},$$
(9.18)

where $EC(C_i, C_j)$ is the sum of the edges (of the k-nearest neighbor graph) that connect clusters C_i and C_j ; $EC(C_i)$ is the minimum sum of the cut edges if we bisect cluster C_i ; and $EC(C_j)$ is the minimum sum of the cut edges if we bisect cluster C_j .

02/14/2018

Introduction to Data Mining, 2nd Edition

Relative Closeness

• Relative Closeness (RC) is the absolute closeness of two clusters normalized by the internal closeness of the clusters. Two clusters are combined only if the points in the resulting cluster are almost as close to each other as in each of the original clusters. Mathematically,

$$RC = \frac{\bar{S}_{EC}(C_i, C_j)}{\frac{m_i}{m_i + m_j} \bar{S}_{EC}(C_i) + \frac{m_j}{m_i + m_j} \bar{S}_{EC}(C_j)},$$
(9.17)

where m_i and m_j are the sizes of clusters C_i and C_j , respectively, $\bar{S}_{EC}(C_i, C_j)$ is the average weight of the edges (of the k-nearest neighbor graph) that connect clusters C_i and C_j ; $\bar{S}_{EC}(C_i)$ is the average weight of edges if we bisect cluster C_i ; and $\bar{S}_{EC}(C_j)$ is the average weight of edges if we bisect cluster C_j . (EC stands for edge cut.)

02/14/2018

Introduction to Data Mining, 2nd Edition

55

Chameleon: Steps

Preprocessing Step:

Represent the data by a Graph

- Given a set of points, construct the k-nearestneighbor (k-NN) graph to capture the relationship between a point and its k nearest neighbors
- Concept of neighborhood is captured dynamically (even if region is sparse)
- Phase 1: Use a multilevel graph partitioning algorithm on the graph to find a large number of clusters of well-connected vertices
 - Each cluster should contain mostly points from one "true" cluster, i.e., be a sub-cluster of a "real" cluster

02/14/2018

Introduction to Data Mining, 2nd Edition

Chameleon: Steps ...

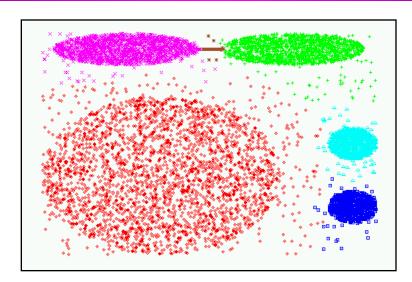

- Phase 2: Use Hierarchical Agglomerative Clustering to merge sub-clusters
 - Two clusters are combined if the resulting cluster shares certain properties with the constituent clusters
 - Two key properties used to model cluster similarity:
 - Relative Interconnectivity: Absolute interconnectivity of two clusters normalized by the internal connectivity of the clusters
 - Relative Closeness: Absolute closeness of two clusters normalized by the internal closeness of the clusters

Graph-Based Clustering: SNN Approach

Shared Nearest Neighbor (SNN) graph: the weight of an edge is the number of shared neighbors between vertices given that the vertices are connected

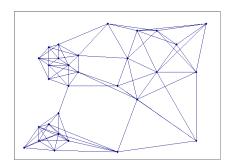

02/14/2018

Introduction to Data Mining, 2nd Edition

65

Creating the SNN Graph

Sparse Graph

Shared Near Neighbor Graph

Link weights are similarities between neighboring points

Link weights are number of Shared Nearest Neighbors

02/14/2018

Introduction to Data Mining, 2nd Edition

Jarvis-Patrick Clustering

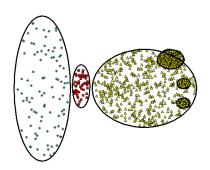

- First, the k-nearest neighbors of all points are found
 - In graph terms this can be regarded as breaking all but the k strongest links from a point to other points in the proximity graph
- A pair of points is put in the same cluster if
 - any two points share more than T neighbors and
 - the two points are in each others k nearest neighbor list
- For instance, we might choose a nearest neighbor list of size 20 and put points in the same cluster if they share more than 10 near neighbors
- Jarvis-Patrick clustering is too brittle

02/14/2018

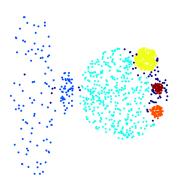

Introduction to Data Mining, 2nd Edition

67

When Jarvis-Patrick Works Reasonably Well

Original Points

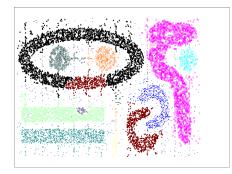

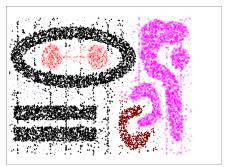

Jarvis Patrick Clustering 6 shared neighbors out of 20

Smallest threshold, T, that does not merge clusters.

Threshold of T-1

02/14/2018

Introduction to Data Mining, 2nd Edition

69

SNN Density-Based Clustering

- Combines:
 - Graph based clustering (similarity definition based on number of shared nearest neighbors)
 - Density based clustering (DBSCAN-like approach)
- SNN density measures whether a point is surrounded by similar points (with respect to its nearest neighbors)

02/14/2018

Introduction to Data Mining, 2nd Edition

SNN Clustering Algorithm

1. Compute the similarity matrix

This corresponds to a similarity graph with data points for nodes and edges whose weights are the similarities between data points

Sparsify the similarity matrix by keeping only the k most similar neighbors

This corresponds to only keeping the *k* strongest links of the similarity graph

3. Construct the shared nearest neighbor graph from the sparsified similarity matrix.

At this point, we could apply a similarity threshold and find the connected components to obtain the clusters (Jarvis-Patrick algorithm)

4. Find the SNN density of each Point.

Using a user specified parameters, *Eps*, find the number points that have an SNN similarity of *Eps* or greater to each point. This is the SNN density of the point

02/14/2018

Introduction to Data Mining, 2nd Edition

71

SNN Clustering Algorithm ...

5. Find the core points

Using a user specified parameter, *MinPts*, find the core points, i.e., all points that have an SNN density greater than *MinPts*

6. Form clusters from the core points

If two core points are within a "radius", *Eps*, of each other they are placed in the same cluster

7. Discardall noise points

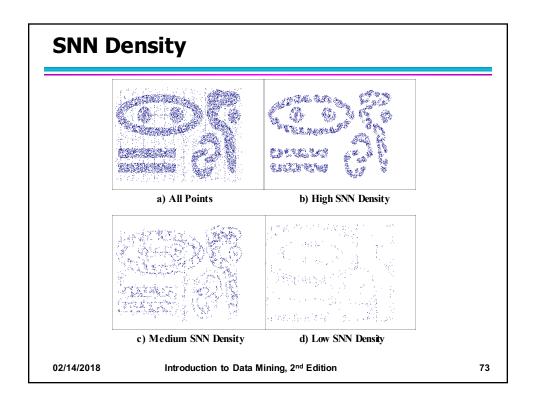

All non-core points that are not within a "radius" of *Eps* of a core point are discarded

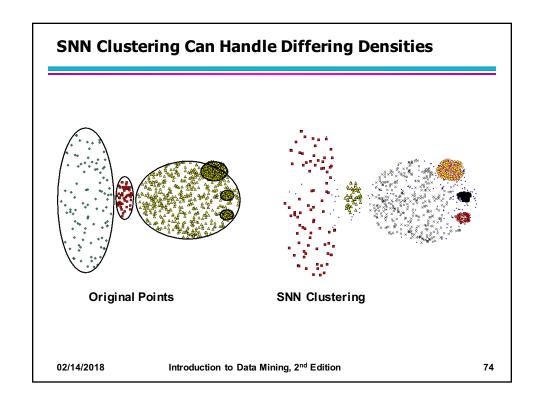

8. Assign all non-noise, non-core points to clusters
This can be done by assigning such points to the
nearest core point

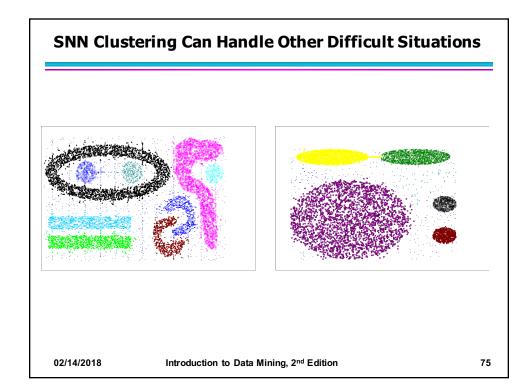

(Note that steps 4-8 are DBSCAN)

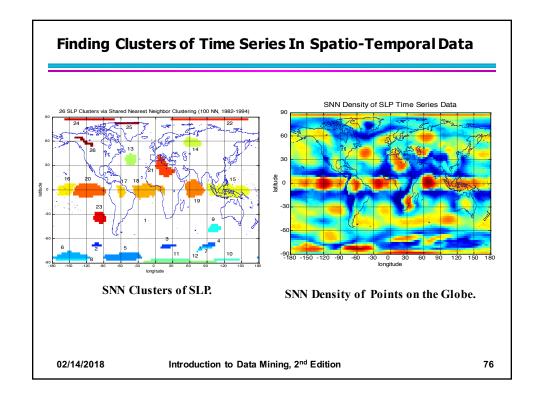

02/14/2018

Introduction to Data Mining, 2nd Edition

Limitations of SNN Clustering

- Does not cluster all the points
- Complexity of SNN Clustering is high
 - O(n * time to find numbers of neighbor within Eps)
 - In worst case, this is O(n²)
 - For lower dimensions, there are more efficient ways to find the nearest neighbors
 - R* Tree
 - k-d Trees
- Parameteriziation is not easy

- Non-determinism
- Parameter selection
- Scalability
- Underlying model
- Optimization based approach

02/14/2018

Introduction to Data Mining, 2nd Edition

81

Comparison of MIN and EM-Clustering

- We assume EM clustering using the Gaussian (normal) distribution.
- MIN is hierarchical, EM clustering is partitional.
- Both MIN and EM clustering are complete.
- MIN has a graph-based (contiguity-based) notion of a cluster, while EM clustering has a prototype (or model-based) notion of a cluster.
- MIN will not be able to distinguish poorly separated clusters, but EM can manage this in many situations.
- MIN can find clusters of different shapes and sizes; EM clustering prefers globular clusters and can have trouble with clusters of different sizes.
- Min has trouble with clusters of different densities, while EM can often handle this.
- Neither MIN nor EM clustering finds subspace clusters.

02/14/2018

Introduction to Data Mining, 2nd Edition

Comparison of MIN and EM-Clustering

- MIN can handle outliers, but noise can join clusters; EM clustering can tolerate noise, but can be strongly affected by outliers.
- EM can only be applied to data for which a centroid is meaningful; MIN only requires a meaningful definition of proximity.
- EM will have trouble as dimensionality increases and the number of its parameters (the number of entries in the covariance matrix) increases as the square of the number of dimensions; MIN can work well with a suitable definition of proximity.
- EM is designed for Euclidean data, although versions of EM clustering have been developed for other types of data. MIN is shielded from the data type by the fact that it uses a similarity matrix.
- MIN makes no distribution assumptions; the version of EM we are considering assumes Gaussian distributions.

Introduction to Data Mining, 2nd Edition

83

Comparison of MIN and EM-Clustering

- EM has an O(n) time complexity; MIN is O(n²log(n)).
- Because of random initialization, the clusters found by EM can vary from one run to another; MIN produces the same clusters unless there are ties in the similarity matrix.
- Neither MIN nor EM automatically determine the number of clusters.
- MIN does not have any user-specified parameters; EM has the number of clusters and possibly the weights of the clusters.
- EM clustering can be viewed as an optimization problem;
 MIN uses a graph model of the data.
- Neither EM or MIN are order dependent.

Introduction to Data Mining, 2nd Edition

Comparison of DBSCAN and K-means

- Both are partitional.
- K-means is complete; DBSCAN is not.
- K-means has a prototype-based notion of a cluster; DB uses a density-based notion.
- K-means can find clusters that are not well-separated.
 DBSCAN will merge clusters that touch.
- DBSCAN handles clusters of different shapes and sizes;
 K-means prefers globular clusters.

Introduction to Data Mining, 2nd Edition

85

Comparison of DBSCAN and K-means

- DBSCAN can handle noise and outliers; K-means performs poorly in the presence of outliers
- K-means can only be applied to data for which a centroid is meaningful; DBSCAN requires a meaningful definition of density
- DBSCAN works poorly on high-dimensional data; Kmeans works well for some types of high-dimensional data
- Both techniques were designed for Euclidean data, but extended to other types of data
- DBSCAN makes no distribution assumptions; K-means is really assuming spherical Gaussian distributions

Introduction to Data Mining, 2nd Edition

Comparison of DBSCAN and K-means

- K-means has an O(n) time complexity; DBSCAN is O(n^2)
- Because of random initialization, the clusters found by Kmeans can vary from one run to another; DBSCAN always produces the same clusters
- DBSCAN automatically determines the number of clusters; K-means does not
- K-means has only one parameter, DBSCAN has two.
- K-means clustering can be viewed as an optimization problem and as a special case of EM clustering; DBSCAN is not based on a formal model.
